Comparison of first configuration (black) and second configuration (red)  
Along the X-axis

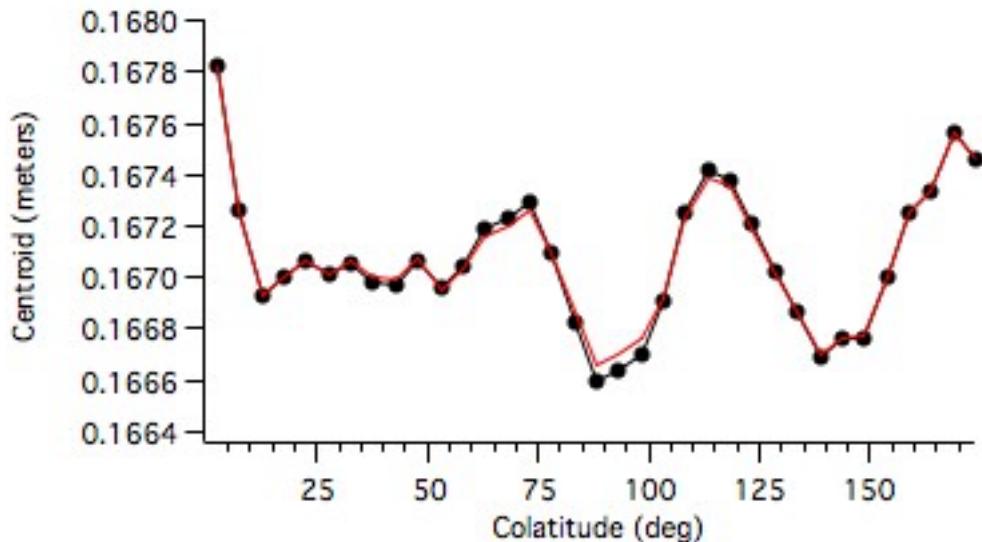

Figure 5. Comparison of Figure 1 (black) and Figure 3 (red).

The two configurations are almost identical with a very small change near the equator (90 deg).

Each point is an average over one revolution of the satellite. The colatitude changes by about 5 degrees on each revolution. The direction of the incident beam does not change much near the poles. These points do not give a good average because of the angular coordinate system. The points near the equator give a good average. The change in the black line from Colatitude 88 to 113 deg the peak to peak change is .8 millimeters. This is within the design goal of one millimeter.

Comparison of first configuration (black) and second configuration (red)  
Along the X-axis

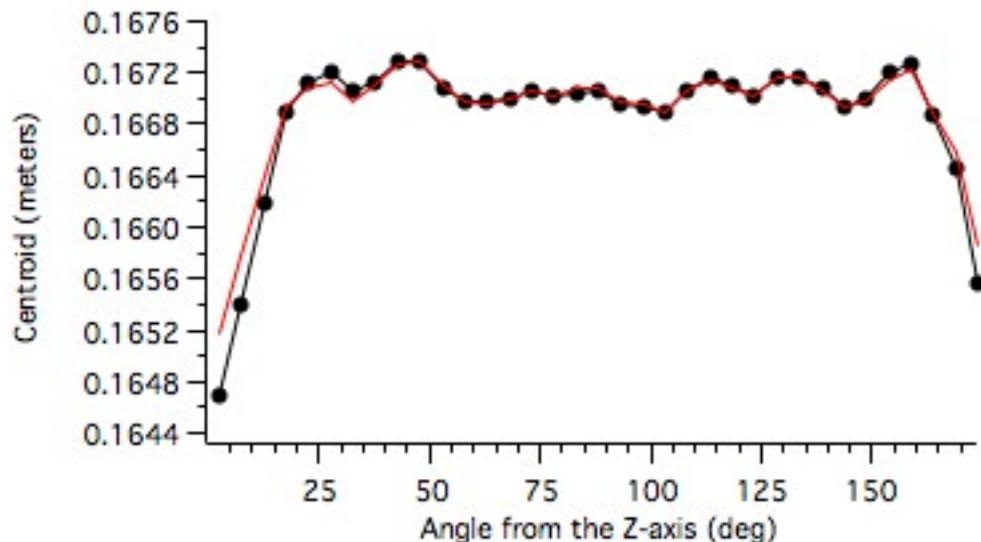

Figure 6. Comparison of Figure 2 (black) with Figure 4 (red)

The two configurations are almost identical except near the +Z and -Z axes on the equator. The middle of the curve is very stable. The peak to peak change over the whole plot is about 2 mm. However, excluding the first 3 and the last 3 points the changes are only .4 mm peak to peak. The first and last points are on the equator and have poor averaging because of the angular coordinate system. The poles are at 90 degrees and have good averaging.

### First configuration
